

Mitcham Common

Report on a ground invertebrate survey, 15 November 2006 – 15 November 2007.

Edward Milner B Sc, MIEEM

1. Introduction

Mitcham Common is a large public open space in the London Borough of Merton. It includes some undisturbed areas of acid grassland, part of which is a golf course, as well as a good deal of secondary woodland and recreational grassland of mixed history and management. Capped landfill covers substantial areas, but as with other nutrient-rich created habitats these sectors have so far developed into rank stands of tall herbs of little conservation interest. The golf course and some other areas include areas of heather and dwarf gorse. There are also some ponds and damp areas including areas of *Molinia* tussocks, some of which become regularly waterlogged in winter.

The purpose of this survey was to make an assessment of the conservation value of selected parts of the Common, including some of the acid grassland areas, by concentrating on ground-active invertebrates (spiders, beetles, pseudoscorpions), looking out for species of particular interest. In the light of this preliminary survey some recommendations for future management for these and other grassland areas were to be made. It was also the intention to bring the spider list for the Common up to date and to make it more comprehensive. Two previous reports on invertebrates on the Common were prepared in 1984 and 1991, but spider records only made up a small part of each.

The earlier report (Morris, 1984) includes a number of records which I have rejected, in consultation with Peter Harvey (National Recording Scheme Organiser) as needing confirmation of their identification. The author of the spider section of the 1984 report, Mr A.D.Sclater indicates that a number of specimens were identified by Mr P Hillyard (Natural History Museum) and Dr P Merrett (ITE). However several of the more difficult species (that could have been confused with other, commoner species), and the rarer, more unlikely species were not, apparently, forwarded to either for confirmation.

In the later report (Morris, 1991) a number of species not found in the present survey were recorded. However as these are all both relatively easy to identify and likely to have been found on the Common, these records (including the Notable A *Bianor aurocinctus*, recorded from several acid grassland sites in the west London area) are accepted.

2. Materials and Methods

The survey concentrated on four discrete sectors of the Common (see Table 1). A total of 11 trap-sites were sampled, all in grassland sites except site 06 (Golf Course 2) which was in dense heather (*Calluna vulgaris*). All the sites were unmown except 07 (Seven Islands 1).

Table 1: Habitat Compartments and trap-sites

Sector	Habitat	No.of Trap-sites	Trap-sites
Gun-site (west)	Acid grassland with anthills	3	01,02,011
Gun-site (centre)	Acid grassland with anthills	2	03,04
Golf Course	Acid grass and heather (<i>Calluna vulgaris</i>)	2	05,06
Seven Islands	Damp tussock (<i>Molinia caerulea</i>) grassland (partly mown)	3	07,08
Mill House	Acid grassland with dwarf gorse, and anthills	2	09,10

Pitfall traps were set in standard trios with a small quantity of ethylene glycol (holding agent) and commercial detergent (wetting agent). These compounds may act as an attractant for some species and discourage others but this standard form has been used throughout London in previous surveys and presumably the same bias (if any) occurs each time. All the traps were emptied on a monthly basis for a whole year (December 2006 to November 2007) so that the catch represented exactly a 12-month period. At two sites (01 and 11) this was not possible and more limited periods were sampled.

Spiders were identified by the author, beetles by Mr N Heal, and the pseudoscorpions by Dr G Legg.

3. Results

The total numbers of spiders and number of species in 3 groups trapped (spiders, beetles and pseudoscorpions) were as follows:

Spiders (Table 2A) : 3829 individuals, representing 86 spp. including one Nationally Notable A species (*Argiope bruennichi*) and one Nationally Notable B (*Centromerus incilium*). However several other species are rare in the regional context of greater London (see below).

As a result of the trapping the number of spiders recorded for the Common is now 123 plus six regarded as unconfirmed (*Tetragnatha obtusa*, *Pardosa amentata*, *Pirata piraticus*, *Tegenaria agrestis*, *Clubiona pallidula*, *Clubiona brevipes*), together with one species *Pholcus phalangioides* found exclusively inside the buildings, giving a grand total of 130 species (see **Table 5**). Following discussion with the warden, Martin Boyle, a number of other species claimed to have been found on the Common (such as *Nigma puella*, *Xerolycosa nemoralis* and *Sitticus caricis*) are provisionally rejected as their identifications remain unconfirmed.

Beetles (Table 3) 151 spp. trapped including 3 Notable A spp. (*Platynaspis luteorubra*: Coccinellidae; *Longitarsus luridus*: Chrysomelidae; *Ceutorhynchus atomus*: Curculionidae), and 8 Notable B spp. (*Panagaeus bipustulatus*, *Platyderus ruficollis*: Carabidae; *Acidota cruentat*, *Liogluta pagana*: Staphylinidae; *Cassida prasina*, *Longitarsus dorsalis*: Chrysomelidae; *Cneorhinus plumbeus*, *Otiorhynchus raucus*: Curculionidae.)

Pseudoscorpions: 1 sp. *Chthonius ischnosceles*. A common and widespread species in the London area.

4. Interpretation of the results

Of the groups involved, spiders have proved to be sensitive indicators of both minor variations in the habitat and of management practice. This is probably because in general most species apart from specific ‘pioneers’ tend to remain in an area that suits them – for example several species are associated with ants and are usually found within a metre or two of the nearest anthill. Beetles are much more mobile, especially carnivorous species although obviously many phytophagous species tend to be found on or near their preferred food plants. The pseudoscorpion *Chthonius ischnosceles* occurs more frequently in woodland but it is also found in grassland as well as disturbed habitats so that its presence has little ecological significance.

Beetles

Most of the beetles species found in this survey are widespread in London and commonly found in London grasslands. Many beetles are also extremely mobile so that their occurrence in pitfall traps is less easy to interpret than spider results. Among the phytophagous species recorded several are associated with the characteristic plants of the Common.

Examples are: yarrow – *Achillea millefolium* (beetle: *Cassida prasina*); Sheep’s Sorrel – *Rumex acetosella* (beetles: *Apion rubens*, *Perapion marchicum*, *Rhinoncus castor*), and gorse – *Ulex* spp. (beetles: *Exapion ulicis*, *Sitona regensteinensis*). One of the weevils (*Cneorhinus plumbeus*) is associated with the scarce herb saw-wort (*Serratula tinctoria*), which occurs in the Gun Site area.

Spiders

Table 2A gives the summary of results of the spider trapping. Total numbers were somewhat lower than at other similar sites elsewhere in London, varying (for the seven grassland sites excluding Seven Islands (07 and 08) and site 06) from 241 to 649. The two Seven Islands sites were particularly disappointing only producing 121 and 175 spiders respectively.

In terms of species richness (No. of species) however, the grassland sites on the Common were very promising with a mean for the seven sites being almost 40. Selected other sites in the London area (Table 2B) show how unusual this is; only very rarely are scores of over 40 achieved for a 12-month trapping period, yet here this figure was reached at sites 03, 04, 05 and 09) as well as at the site under heather 06.

For grassland spiders a system of weighting giving different values to species of high conservation value and negative values for pioneer species characteristic of disturbed and damaged sites has been devised (Milner, 2005). It is based on national and regional local occurrence as well as degree of habitat specialisation. Applying this scoring system, a series of weighted scores (S1 and S2) are calculated. For the Common these scores were also higher than at most other London sites. What this means is that the conservation value of the species found is high, suggesting that the grassland surveyed is in good health.

From the last column in Table 2A it can be seen that the wolf spider *Pardosa pullata* is consistently the most abundant species from all the trap-sites, with the tiny Hahniid *Hahnia nava* being the second most abundant at four out of seven grassland sites. This alone suggests that the areas sampled are not badly disturbed by mowing, overgrazing or trampling. Grassland in public open spaces in London, even the more ‘natural’ ones often have an abundance of pioneer and disturbed ground species (which have negative scores) depressing

their S1 and S2 scores. Common pioneers (such as *Oedothorax fuscus*, *Erigone dentipalpis* and *Milleriana inerrans*) that thrive in disturbed grassland, are virtually absent on the surveyed parts of Mitcham Common. While this means that the total number of species (S in Tables 2A and 2B) may be one or two lower than would otherwise be the case, the weighted scores are higher.

As Tables 2A and 2B show, the weighted scores (S1 and S2) and Grassland Conservation Value (GCV) of several sites at Mitcham Common are among the highest so far recorded in London grasslands (although Table 2B does not show Hounslow Heath, or a number of other high quality sites trapped more recently). This is in spite of the fact that while the scarce *Centromerus incilium* is almost ubiquitous on the Common, particularly rare species with high scores such as *Tapinocyboides pygmaeus* or *Zelotes petrensis* have not been found.

Table 4 gives the data from each trap-site in detail. Some interesting differences between different parts of the Common are revealed. Among the grassland specialists the Notable *Centromerus incilium* was trapped at all sites except 08, and the relatively scarce *Agroeca inopina* at all sites except 07 and 08, and the scarce *Agroeca brunnea* was trapped at four sites: 03 and 04 at the Gun site, and both sites (09 and 10) at Mill house. *Argenna subnigra* was trapped in large numbers at Mill house (56 individuals!) and sparingly at the Gun-site and at site 06 under heather. This spider is very scarce in London and only found on relic acid grassland sites that have remained relatively undisturbed. The scarce grassland money spider *Ceratinopsis stativa* was trapped at Sven Islands and also at Mill house (09) but not elsewhere. The ant-associated species *Zelotes latreillei* was trapped at all 11 sites, and the second ant-associated species *Drassyllus pusillus* at all except the Seven Islands sites (too damp) and site 10. The gun-site area (sites 01-04 and 11) also had both the small ant-mimics *Micaria pulicaria* and *Phrurolithus festivus* as did site 09 (Mill House), whereas the rarer ant-associated *Steatoda phalerata* was trapped at two places on the Gun-site and both trap-sites on the golf course.

No important spiders were found exclusively at the Gun-site but some scarcer species absent from the Gun Site were found elsewhere. Two wolf spiders, *Pardosa nigriceps* and *Pardosa saltans* both occurred at the two golf-course sites and while two specimens of *P. nigriceps* were trapped at site 10 (Mill House), neither species was seen elsewhere. *Hahnia nava* was common everywhere, but at site 3 (Golf Course) and site 10 (Millhouse, a second, scarcer species *H. montana* was trapped. The uncommon wolf spider *Alopecosa cuneata* was trapped in the centre of the Gun-site (030 and 04) and a single specimen was taken at Seven Islands but it was not seen elsewhere. Two small crab-spiders *Ozyptila sanctuaria* and *O. simplex* were both trapped at most sites except Seven Islands (probably too damp). The rare (in London) *Haplodrassus signifer*, a relic grassland species *par excellence*, was trapped at three of the Gun-site trap sites and a single specimen was also taken at Mill House (site10).

4. Conclusions and implications for management and further study.

The main sites from Gun-site (trap-sites 01,02,03,04 and 11), the golf-course rough (site 05), and the two Mill-House sites are all good examples of old acid grassland assemblages with common ant-associated species (*Zelotes latreillei*, *Drassyllus pusillus*, and *Micaria pulicaria*), and a number of other species restricted (in the London area) to this habitat. Among these are several species that are uncommon or even rare in London: *Centromerus incilium*, *Steatoda phalerata*, *Haplodrassus signifer*, *Drassodes cupreus* and *Argenna subnigra* are all known only from a handful of such sites in the London area.

It is worth noting however that several of the rarer grassland specialists found at some old grassland sites in London have not been found at Mitcham Common. These include *Atypus affinis* (the Tube-Web Spider), other *Zelotes* spp., *Bianor aurocinctus* and *Tapinocyboides paygmaeus* etc)

Of the sites trapped, the Gun-site area is rich in grassland spiders, although few rarities are present. There is a good number of anthills and the grazing by rabbits maintains a diverse sward which is not (or only very slowly) reverting to woodland. The golf-course rough is potentially more interesting, partly because of the diverse vegetation, with patches of gorse as well as the areas of heather. The Mill house area scored highly (Table 2A) again due to the diversity of vegetation and lack of disturbance.

The most disappointing area was clearly Seven Islands. In November part of the area had been machine-mown, even though this is a damp area of well-developed *Deschampsia cespitosa* tussocks, which becomes waterlogged later in the winter. The spider fauna should be rich but was found to be considerably poorer than the other areas trapped. This is almost certainly due to periodic disturbance such as that caused by machine mowing.

The implications for management for all the areas investigated (except for Seven Islands) are that as far as possible the present conditions should be maintained. In general rabbits can be encouraged as they keep the sward diverse and in good condition for spiders and (to some extent) hold back bramble and discourage the establishment of tree seedlings. More specific recommendations are given below.

Gun-site

Some slow colonisation by oak is taking place in open areas in spite of the rabbits and this should be controlled by removing these young trees instead of coppicing them. Tree seedlings, which become established in thickets and among tall herbs should also be removed. Bramble invasion may also need to be discouraged. There is constant eutrophication of habitats in the London area generally and this is made worse by the excreta of dogs. This again may be a slow process but a damaging one still, so perhaps notices and dog waste bins could be placed at the entrance points, with the notices pointing out the damage that extra nitrogen and phosphorus will do.

During the survey period it was found that large orb-web spiders were very scarce or absent (although recorded by Morris, 1984 from unspecified parts of the Common). The possibility of reintroduction of *Larinoides cornutus* and *Araneus quadratus* should be considered.

Golf-course roughs

The sampling did not cover the main unmown parts of the golf-course but potentially these areas are very interesting, with patches of genuine dry heathland and further undisturbed acid grassland, as well as the gorse and heather. Maintaining a good age structure of both is important, and this should always include some over-mature areas which can act as reservoirs for numerous species of both insects and spiders. Further study of the golf course roughs is suggested, especially under gorse and in the larger dry areas of grass and any damp zones.

Seven Islands

This area was disappointing, due probably to the current mowing regime. The tussock areas should not be mown at all, although it may take a long time for the fauna to recover. Since the area becomes waterlogged in the winter many species will use the dead stems and seed stalks as places to overwinter or lay eggs. Dead fruiting stems may also become the preferred habitat of a number of spiders. Machine-mowing also causes ground disturbance and compaction, and effectively damages the entire ecosystem.

Mill house

Two areas were sampled: the area almost completely enclosed by gorse bushes near the main road, and an area of rough and fairly natural grass with anthills and tussocks to the east of the large meadow. The first site has a good development of dwarf gorse, excellent for spiders and a plant that effectively discourages most dogs! Both areas are in good condition, are very little disturbed and in spite of apparent absence of rabbits (?) there has been only limited invasion by oak. Bramble, on the other hand may be increasing and probably needs some attention. Additional planting of gorse is suggested, and possibly the development of some hedges of native woody plants, something that is lacking from much of the Common.

Table 5:A complete list of spiders recorded from Mitcham Common

Date given is that of the first record (if known)

First column is National Conservation Status

Fourth column is reference No from present survey

Last column is origin of record:

em = E Milner (present survey etc.)

M1 = Morris (1984)

M2 = Morris (1991)
